Learning-Augmented Online Algorithms

- **Online algorithm** makes online decisions when inputs are revealed **piece-by-piece** and **future input pieces are unknown**

- competitive ratio

$$\text{CR} = \max_I \frac{\text{OPT}(I)}{\text{ALG}(I)}$$

offline optimal

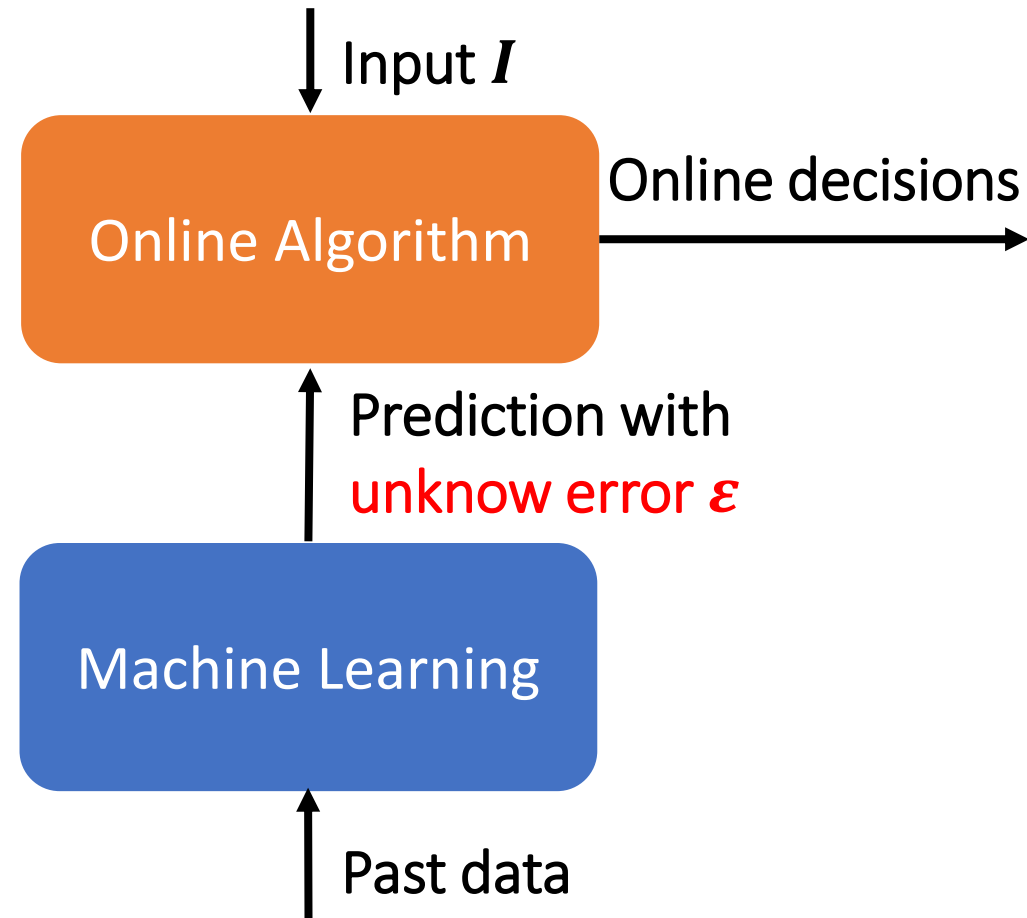

online algorithm

- **Learning-augmented algorithm** leverages predictions about the future

- competitive ratio as a function of ε

$$\text{CR}(\varepsilon) = \max_I \frac{\text{OPT}(I)}{\text{ALG}(I, \varepsilon)}$$

Learning-augmented algorithm when prediction error is ε

Two Important Metrics: Consistency and Robustness

Concepts

- $CR(0) \leq \eta$ (consistency)
- $\max_{\varepsilon} CR(\varepsilon) \leq \gamma$ (robustness)

Trade-offs

Pareto-optimality

- for a given robustness, **no online algorithms** can achieve a better consistency

Can we design learning-augmented algorithms with **bounded robustness and consistency** for other online problems?

Yes, secretary and online matching [Antoniadis2020, NeurIPS], metrical task systems [Antoniadis2020, ICML], etc.

Can we design **Pareto-optimal** learning-augmented algorithms for other online problems?

Only known for ski rental problem

Our contribution: we design **Pareto-optimal** algorithms for **online conversion problems**

Online Conversion Problem

- Exchange one asset (e.g., one dollar) to another asset over time varying exchange rates
 - For $n = 1, \dots, N$
 - observe an exchange rate (or price) v_n
 - decide the amount of dollar to trade, $x_n \in \mathcal{X}_n$, and obtain return $x_n v_n$
 - Goal: maximize the total return $\sum_{n \in [N]} x_n v_n$
- 1-max-search: $\mathcal{X}_n = \{0,1\}$
one-way trading: $\mathcal{X}_n = [0,1]$

Unified Online Threshold-Based Algorithm (OTA)

- Initialization

- threshold $\phi(w): [0,1] \rightarrow [L, U]$

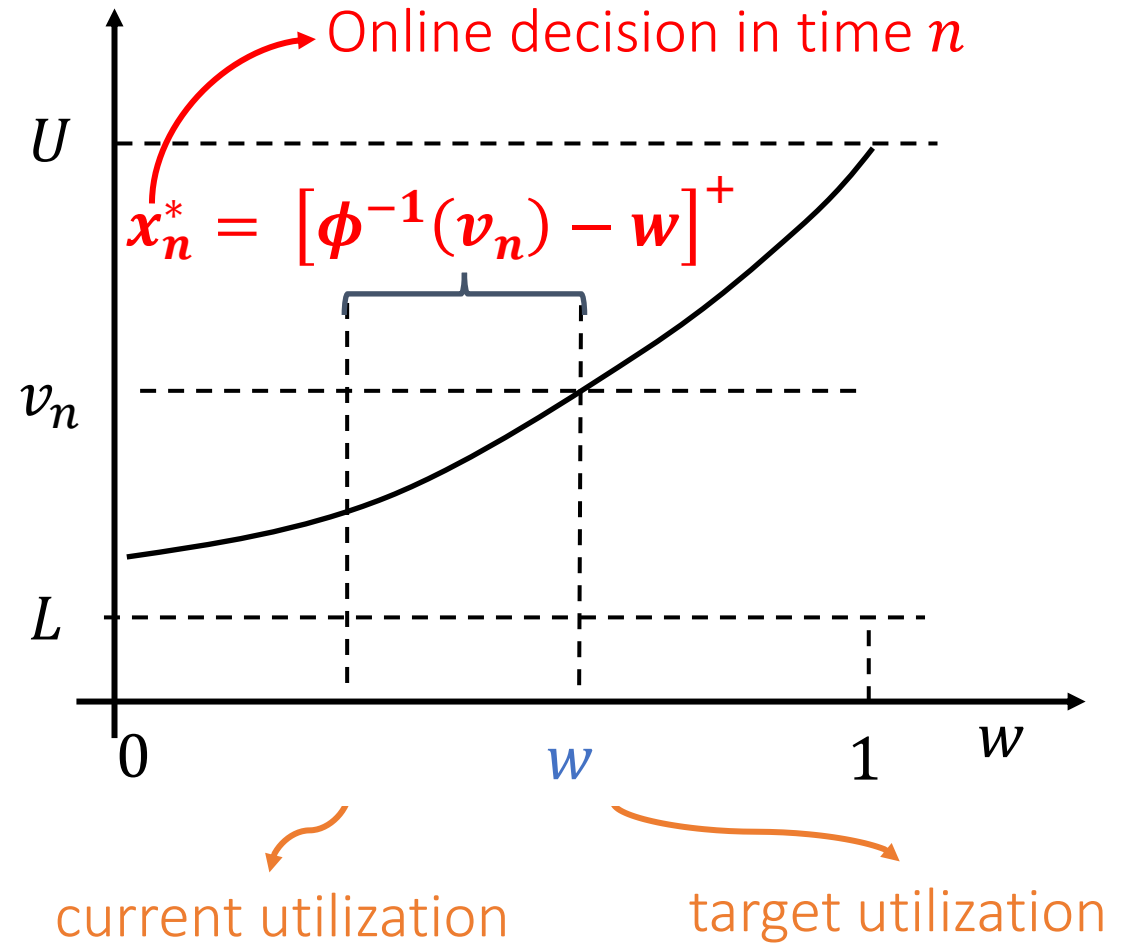

utilization (cumulative traded dollar)

- For each n do

- observe current utilization w and exchange rate v_n
- determine x_n^* by solving

$$\max_{x_n \in \mathcal{X}_n} v_n x_n - \int_{w^{(n-1)}}^{w^{(n-1)} + x_n} \phi(u) du$$

- update $w \leftarrow w + x_n^*$

Design of Threshold Function for OTA

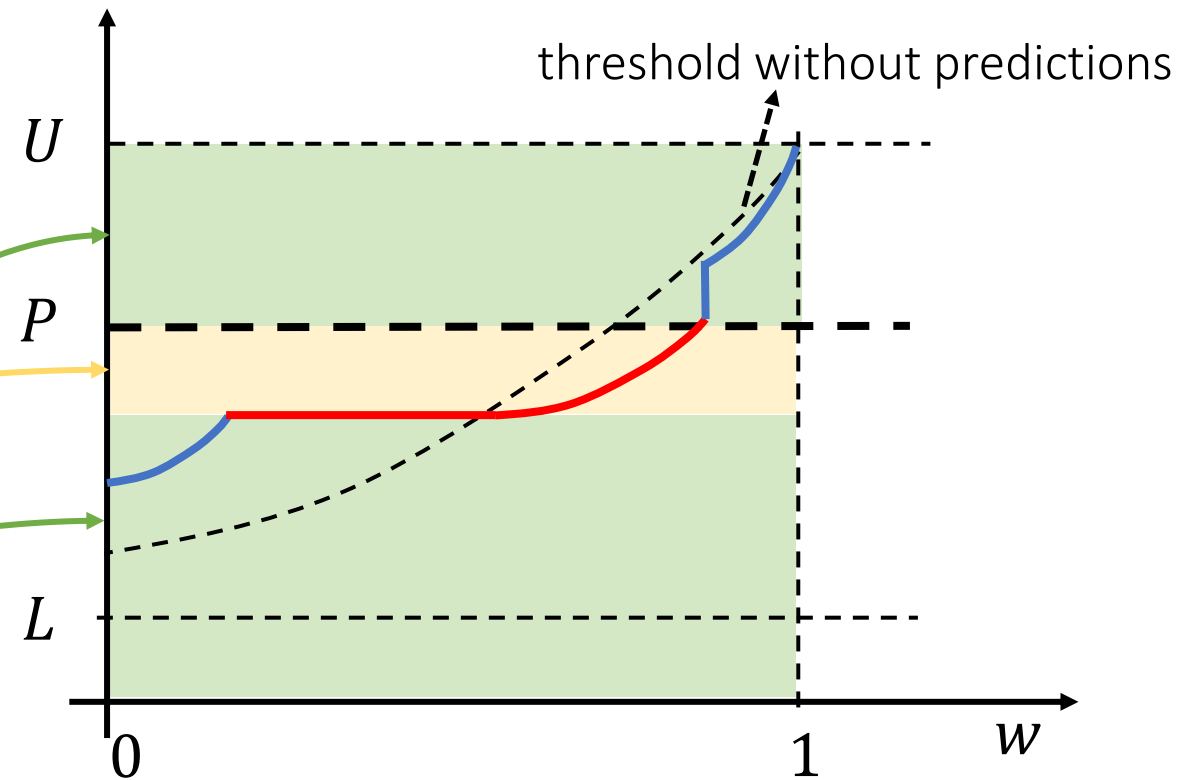

Given a prediction of the **maximum exchange rate P** ,
how to incorporate it into the threshold function to
guarantee **robustness and consistency**?

Threshold Function for Learning-Augmented OTA

- The threshold function consists of multiple segments

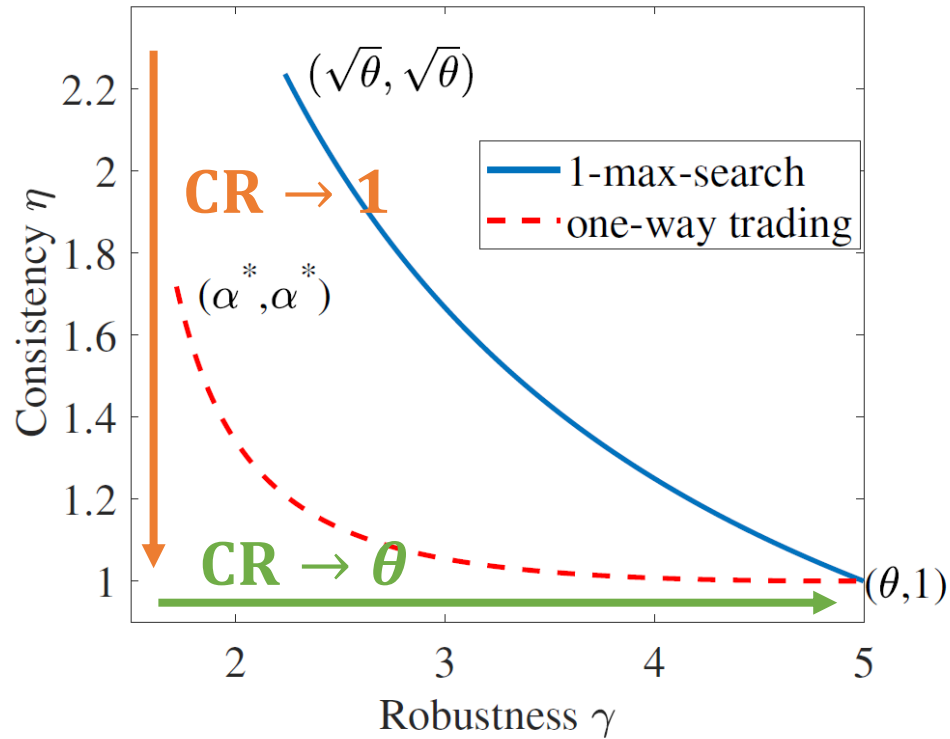

- price region near prediction P , ensure consistency
- price region away from prediction P , ensure robustness

Theorem (sufficient conditions):

If each segment satisfies a set of [differential equations](#), learning-augmented OTA is with consistency and robustness upper bounds.

Pareto-Optimal Learning-Augmented OTA

- As consistency improves $\text{CR} \rightarrow 1$ (best possible ratio), robustness degrades $\text{CR} \rightarrow \theta$ (worst possible ratio)
- Pareto boundary of one-way trading dominates that of 1-max-search

Theorem (Pareto-Optimality):

Learning-augmented OTA is Pareto-optimal, i.e., for a given robustness, no online algorithms can achieve a better consistency

Take-Away Message

We have designed **Pareto-optimal** learning-augmented **threshold-based algorithms** for **online conversion problems**
